Recent links

Multidimensional linear and truncated differential

Collision probability as nonuniformity measure

Sampling without replacement

Conclusions

# Cryptanalysis at the design phase

- ▶ All known cryptanalysis as applicable to the new design
- ▶ Add reasonable security margin  
For example, add more rounds to iterated block ciphers

# Lightweight ciphers

- ▶ Optimized with respect to platform specific performance requirements
  - ▶ Secure: Resistant against all known cryptanalytic attacks
- ⇒ Minimize security margins
- ⇒ Must acquire better estimates for complexity of cryptanalytic attacks

# Statistical cryptanalysis of iterated block ciphers

## Differential cryptanalysis<sup>1</sup>

- ▶ chosen-plaintext attack
- ▶ data complexity upperbounded based on the best differential probability
- ▶ historical note: ciphertext-only differential cryptanalysis using index of coincidence [Friedman 1922]

## Linear cryptanalysis<sup>1</sup>

- ▶ known-plaintext attack
- ▶ data complexity upperbounded based on the largest magnitude of linear correlation (or bias, “linear probability”)

<sup>1</sup> Obvious references omitted

# Differential probability of cipher $E$

- ▶  $\alpha$  difference in plaintext  $x$
- ▶  $\beta$  difference in ciphertext  $E(x)$
- ▶  $\Pr[\alpha \rightarrow \beta]$  probability that given  $\alpha$  we observe ciphertext difference  $\beta$

$$E(x + \alpha) + E(x) = \beta$$

$$\Pr[\alpha \rightarrow \beta] = \sum_x p_\chi(\alpha \rightarrow \beta)$$

where  $\chi = (\alpha = \chi_0, \chi_1, \dots, \chi_r = \beta)$  is a differential characteristic  $\chi$  from  $\alpha$  to  $\beta$  and (assuming round independence)

$$p_\chi(\alpha \rightarrow \beta) = \prod_{i=1}^r \Pr[\chi_{i-1} \rightarrow \chi_i]$$

## Linear correlation of cipher $E$

- ▶  $u$  linear mask on plaintext  $x$
- ▶  $v$  linear mask on ciphertext  $E(x)$
- ▶  $\text{cor}[u \rightarrow v]$  correlation between  $u \cdot x$  and  $v \cdot E(x)$

$$\text{cor}[u \rightarrow v] = \sum_{\theta} c_{\theta}(u, v)$$

where  $\theta = (u = \theta_0, \theta_1, \dots, \theta_r = v)$  is a linear characteristic from  $u$  to  $v$  and

$$c_{\theta}(u, v) = \prod_{i=1}^r \text{cor}[\theta_{i-1} \rightarrow \theta_i]$$

Assuming round independence

$$\text{cor}^2[u \rightarrow v] = \sum_{\theta} c_{\theta}^2(u, v) = \sum_{\theta} \prod_{i=1}^r \text{cor}^2[\theta_{i-1} \rightarrow \theta_i]$$

Conclusions

# Computing good estimates

Computation of exact values takes multiplications of huge  $2^n \times 2^n$  matrices

- ▶ transition matrices of Markov processes [Lai-Murphy-Massey 1991]
- ▶ correlation matrices [Daemen 1994], or
- ▶ matrices of squared correlations [N 1994]

see also

N. Linial, Y. Mansour and N. Nisan. Constant depth circuits, Fourier transform, and learnability. Journal of the ACM 40 (3), 607-620 (1993).

# Computing good estimates

In some cases it is possible to exploit the structure of the cipher

- ▶ to make these computations feasible; or
- ▶ to obtain good estimates, or
- ▶ reasonable upperbounds (for security claims)
- ▶ reasonable lower bounds (to bound attack complexity)

In some cases this is really hard

AES: The best known upperbounds for 4 and more rounds obtained by Keliher (2005), Canteaut (2015)

# Provable security theorem

N-Knudsen: Crypto 1992 Rump Session, J Crypt 1995

**Theorem** ( $\mathcal{KN}$ -Theorem) *It is assumed that in a DES-like cipher with  $F : \mathbb{F}_2^m \rightarrow \mathbb{F}_2^n$  the round keys are independent and uniformly random. Then the probability of an  $s$ -round differential,  $s \geq 4$ , is less than or equal to  $2p_{\max}^2$ .*

Here

$$p_{\max} = \max_{\beta} \max_{\alpha \neq 0} \Pr[\alpha \xrightarrow{F} \beta]$$

## CRADIC

Cipher Resistant Against Differential Cryptanalysis  
( $\mathcal{KN}$ -Cipher)

6-round Feistel cipher with round function  $f : \mathbb{F}_2^{32} \rightarrow \mathbb{F}_2^{32}$  based on the power three operation in  $\mathbb{F}_2^{33}$

Jakobsen & Knudsen FSE1997 break it with

- ▶ with 512 chosen plaintexts and  $2^{41}$  running time,
- ▶ or with 32 chosen plaintexts and  $2^{70}$  running time
- ▶ using *higher order differential cryptanalysis*

Round-function based on the inverse mapping not any more resistant.

This approach was then abandoned

... higher algebraic degree does not help if the inverse has a low degree [Boura-Canteaut IEEE Trans. IT 2013].

Round functions based on the exponent function in  $\mathbb{F}_p$  yet to be explored. Previously used for IDEA and SAFER family.

# DEAN

- ▶ Proposed by Baignères et al. 2007
- ▶ Encrypts blocks of nine elements from the additive group  $\mathbb{Z}_{10} \times \mathbb{Z}_{10}$ .
- ▶ Not a complete cipher, no key schedule, 8 rounds
- ▶ One round:

# Linear setting of DEAN

- ▶ Select suitable linear approximation trails through DEAN
- ▶ Use MDS property of `MixColumns` and cover all trails for a minimum number of active S-boxes
- ▶ Restrict the (squared) correlation matrix to this subset
- ▶ obtain an upper bound to the data complexity and also an attack for this data complexity

# Linear approximation of DEAN

# Data complexity estimates

Full code book  $10^{18} \approx 2^{61}$ .

Estimated number of rounds needed to exceed full code book data complexity for a linear distinguisher:

designers	single trail estimate	four rounds
Hakala et al Incrypt 2012	max two MixColumns wide trails and multiple approximations	seven rounds

# PRESENT

- ▶ Proposed by Bogdanov et al. 2007
- ▶ designers: single linear and differential characteristics over more 15 rounds not effective
- ▶ specification has 31 rounds, that is, 16 round margin
- ▶ linear attack on 26 rounds [Cho 2010]
- ▶ the structure allows very accurate estimates of squared linear correlations over any number of rounds [Leander 2011].
- ▶ estimates of differential attacks hard to achieve

# Correlation matrix of S-box of PRESENT

$$\text{cor}[u \xrightarrow{S} v]$$

## LINEAR CONTEXT

Linear Cryptanalysis [Tardy, Gilbert 92] [Matsui 93]

Differential-Linear Cryptanalysis [Langford, Hellman 94]

Square Attack, Integral ... [Daemen, Rijmen, Knudsen 97]

Statistical Saturation [Collard, Standaert 09]

Zero Correlation [Bogdanov, Rijmen 11]

Multiple Linear Cryptanalysis

[Biryukov, de Cannière, Quisquater 04]

Multidimensional Linear Cryptanalysis [Cho, Hermelin, Nyberg 08]

.....

## DIFFERENTIAL CONTEXT

Differential Cryptanalysis [Biham, Shamir 90]

Truncated Differential Cryptanalysis [Knudsen 94]

Higher Order Differential cryptanalysis [Lai 94] [Knudsen 94]

Impossible Differential Cryptanalysis [Knudsen 98]

Multiple Differential Cryptanalysis [Albrecht, Leander 12]

[Blondeau, Gérard, Nyberg 12]

.....

# Truncated differential cryptanalysis

Input difference  $\delta$

Output difference  $\Delta$

Set of input differences:  $\delta \in C$

Set of output differences:  $\Delta \in D$

Probability of truncated differential

$$\frac{1}{|C|} \sum_{\delta \in C} \sum_{\Delta \in D} P[\delta \xrightarrow{F} \Delta]$$

# Multidimensional linear cryptanalysis

Multidimensional linear approximation:

Set of masks  $(u, w) \in U \times W$

Capacity:  $\sum_{u \in U} \sum_{w \in W} \text{cor}_x(u \cdot x + w \cdot y)^2 - 1$

## Recent links

[Leander EC2011] :

Statistical Saturation  $\Leftrightarrow$  Multidimensional Linear

[Bogdanov *et al* AsiaCrypt2012] :

Integral  $\Leftrightarrow$  Zero Correlation Linear

[Blondeau-N EC2013] :

Zero Correlation Linear  $\Leftrightarrow$  Impossible Differential

[Blondeau-N EC2014] :

Multidimensional Linear  $\Leftrightarrow$  Truncated Differential

# Splitting the spaces

Focus on the **left side**:

**multidimensional linear** context

- ▶ all non-zero input and output masks

**truncated differential** context

- ▶ zero input and output differences

Don't care about the **right side**:

**multidimensional linear** context

- ▶ zero input and output masks

**truncated differential** context

- ▶ all input and output differences

# Zero correlation linear

Zero Correlation Linear :

$$\text{cor}_x((a_s, 0), (b_q, 0)) = 0$$

$$\text{for all } (a_s, b_q) \in \mathbb{F}_2^s \times \mathbb{F}_2^q \setminus \{(0, 0)\}$$

# Impossible differential

Truncated Differential:

$$\sum_{\delta_t \in \mathbb{F}_2^t} \sum_{\Delta_r \in \mathbb{F}_2^r} \Pr[(0, \delta_t) \rightarrow (0, \Delta_r)] = 2^{t-q}$$

If  $t=q$  and  $\delta_t \neq 0$

Impossible Differential:

$$\Pr[(0, \delta_t) \rightarrow (0, \Delta_r)] = 0$$

for all  $(\delta_t, \Delta_r) \in \mathbb{F}_2^t \times \mathbb{F}_2^r \setminus \{(0, 0)\}$

# Zero correlation linear and impossible Differential

If  $t = q$

Zero Correlation Linear Distinguisher

is equivalent to

Impossible Differential Distinguisher

# Multidimensional linear and truncated differential

Multidimensional Linear Distinguisher

is equivalent to

Truncated Differential Distinguisher

# The mathematical link

Capacity  $C$  is defined as

$$C = \sum_{(u_s, w_q) \neq 0} \text{cor}[(u_s, 0) \rightarrow (w_q, 0)]^2.$$

Truncated differential probability  $P$  equals

$$P = 2^{-t} \sum_{\delta_t \in \mathbb{F}_2^t} \sum_{\Delta_r \in \mathbb{F}_2^r} \Pr[(0, \delta_t) \rightarrow (0, \Delta_r)]$$

Then it holds [Blondeau-N 2014]

Theorem

$$P = 2^{-q}(C + 1) = 2^s \sum_{x_s, y_q} \Pr(x_s, y_q)^2.$$

# Focus on distributions

Distribution of values  $(x_s, y_q) \in \mathbb{F}_2^s \times \mathbb{F}_2^q$

## Multidimensional linear attack

- ▶ samples plaintexts  $x$  and corresponding ciphertexts  $y$  and examines the nonuniformity of the distribution of values  $(x_s, y_q)$

## Truncated differential attack

- ▶ samples in pairs of plaintexts
- ▶ counts collisions in values  $(x_s, y_q)$

These are just different approaches to sampling of the cipher data and measuring the nonuniformity of the distribution of  $(x_s, y_q) \in \mathbb{F}_2^s \times \mathbb{F}_2^q$ .

## Corollary

Assume that the cipher is secure against classical linear and differential attacks.

### Corollary

The cipher is secure against multidimensional linear attacks if and only if it is secure against truncated differential attacks.

Proof: Provable security requires accurate estimates of correlations of linear approximations (or probabilities of differentials).

# Application to PRESENT

- ▶ PRESENT allows accurate estimation of correlations of its linear approximations over any number of rounds
- ▶ capacities of multidimensional linear approximations can be accurately evaluated
- ▶ The best known linear distinguisher is for 23 rounds and it seems that there is nothing better.

It follows that there is an efficient truncated differential distinguisher for 23 rounds, which can be used in a chosen plaintext key recovery attack.

If PRESENT is secure against linear attacks (as it seems) then it is also secure against differential attacks.

# Outline

Cryptanalysis and lightweight ciphers

Using one differential or linear approximation

Examples

Enhancements using several differentials and linear approximations

Newer statistical cryptanalysis

Recent links

Multidimensional linear and truncated differential

Collision probability as nonuniformity measure

Sampling without replacement

Conclusions

## Sampling without replacement

- ▶ critical for zero-correlation cryptanalysis etc
- ▶ any statistical method gains in accuracy when close to full codebook [Blondeau-N WCC 2015]

# Zero-correlation distinguisher on LBlock (Small Variant)

# Outline

Cryptanalysis and lightweight ciphers

Using one differential or linear approximation

Examples

Enhancements using several differentials and linear approximations

Newer statistical cryptanalysis

Recent links

Multidimensional linear and truncated differential

Collision probability as nonuniformity measure

Sampling without replacement

Conclusions

# Conclusions

- ▶ Lightweight ciphers should allow accurate estimation of resistance against attacks to reduce unnecessary security margins
  - ▶ In this respect, PRESENT turns out to be very good
- ▶ This goal sets also requirements to attack models, which must be accurate. To improve accuracy, use
  - ▶ subsums of linear hulls and differentials instead of single linear and differential characteristics
  - ▶ multiple linear approximations or truncated differentials instead
  - ▶ estimate performance assuming non-repeating plaintext, in particular, when data complexity is close to full codebook.
